

BIODIVERSITY NET GAIN – RIVER METRIC process – step by step flow chart exercise

consider constructability assessment. will this impact on design?

Consider designations, WFD, project proposals, site history, historical mapping

Public access and other users/uses

Understanding working methods and duration of works

Review of baseline ecology

Early engagement with engineers

EIA no net loss. BNG one step beyond.

Funding opportunities

Can we have a conversion from linear to area measurement (& via versa)?

Would headwater wet flushes/ephemeral streams be 'areas' - as maybe <10m either side of watercourse

Think about likely design - how can we avoid impacts

Opportunities for rivers trust to develop and provide services

Is a drain being converted to a wetted flush still a linear river stretch under BNG?

When does a wetted area/flow path become a river for BNG? Does it become a terrestrial area?

Need to understand the whole catchment system - pressures and priorities - how does this inform your BNG objectives...?

cont... are there opportunities in your project area to improve river processes that will achieve BNG further downstream

1. Likelihood of the project scope changing as influenced by stakeholders

Think wider than biodiversity alone. E.g. natural capital and landscape matters, multiple benefits

1. Are there any protected wildlife sites? SSSI, LWS

1. landscape context - look at land use (GSI), risks from SCSMMP or SCSMMP etc? Flood zone - flood risk Flood delineate potential transects (access is relatively low risk)

1. scope a works - planning permission info - have there been any objections or suggestions from consultants?

2. Site access over river?

2. Catchment Partnership Action Plan - is there a plan for the site?

3. river context - typology, find out about reasons for failure if failing

2.0 Wider context: - Landscape context; - Site proposals

3. Before site visit: - River context; - Scope RCA requirements

Historic pictures from the site

Key stakeholder handovers

WINEP obligations/WFD status

2. Site access over river?

2. Linked to LNRS?

2. Catchment Partnership Action Plan - is there a plan for the site?

overview of known pressures

Doesn't focus on WQ + other abiotic factors

Other catchment pressures abstraction etc

3. river context - typology, find out about reasons for failure if failing

3. any designations? Protected site - info from local trusts (Rivers, Wildlife etc)

Conditions of river on the day - be flexible - cancel if bed is not visible etc...

Understanding existing constraints on condition

Is there a control and impact site? A detectable quality gradient? BACI principal

Aligning MoRPhs appropriately based on habitat variability on site

Consider red line boundary - is it likely to change?

Is this an opportunity for Trusts to create income?

Angela talked through a case study on the Mayesbrook project in the workshop

Has the metric been tested against projects delivered in the past?

Long term monitoring in perpetuity

Can 10% net gain really deliver restoration of natural processes?

BIODIVERSITY NET GAIN – RIVER METRIC process – supplementary information

STEP 1 - PRELIMINARY INFORMATION & INVESTIGATIONS (PRE-SITE VISIT) – What's the bigger picture...?

STEP 2 - RIVER CONDITION INVESTIGATIONS – What's needed to assess, understand and improve your River Condition..?

STEP 3 - BM3.0 tool: RIVER METRIC ASSESSMENT (ON SITE) - What's needed to calculate River Metric Units & Net Gain?

STEP 4 - BM3.0 tool: RIVER METRIC ASSESSMENT (OFF SITE*)

Red Stream

- No artificial/managed bank top
- Steep banks
- No bank or bed reinforcement
- Natural bank top and bank face vegetation, including trees
- Invasive species
- Smooth flow
- No in-channel features visible
- Floating vegetation
- Overhanging vegetation
- Some shading
- Fallen trees

Wider channel,
improve
planform,
introduce
gravels

since banks are not reinforced - should be easier to give a natural profile as part of programme of measures

more LWD for more in channel features and flow heterogeneity, also refugia for fish

Condition: Moderate

invasive species removal programme or fund existing work

create in-channel features

berms and gravel seeding to have more flow heterogeneity

fallen trees give this site some more value than Old Brook site

regrade banks so there is more heterogeneity and wet margins

more natural bank profiles

Large wood, riparian planting, marginal scrapes

Old Brook

- Managed bank top
- Reshaped bank face
- No bank or bed reinforcement
- Limited natural bank top and bank face vegetation, some trees
- Invasive species
- Smooth flow
- No in-channel features visible
- Overhanging vegetation
- Shading

buffer
zone.

assess type of banktop
management and draw
up alternative, low
maintenance
management scheme
to benefit riparian
species

Monitoring
and
maintenance
tracking

Raise
bed
level

Re-profile
one bank

Realign?

You could theoretically degrade 1 WFD water body and put all mitigation on another

Does BNG trump WFD?

Old Brook

Red Stream

Re-align the planned route of the road so that it crosses the river perpendicular to the river. This will reduce the length of its impact.

- Rivers
- Existing Road
- Red Line Boundary
- Proposed Realignment
- Proposed Road

You need more vegetation, more shade to the water, add meanders.

Bridge for the road?.. or maybe a culvert under the red stream for the road?

The Red Stream diversion needs to be more diverse in terms of geomorphology and habitat, e.g. add meanders, more in-stream features, backwaters, ponds, native tree planting

Remeander section of Red Brook

Build viaduct over river

Sediment management south of Old Brook - riparian buffer (native species)?

Location of red line boundary is crucial

Question 1: What are you going to do?

Realignment of proposed alignment

Alter the proposed Red Stream culvert design to a wide open span bridge, retaining natural banks

Restore Old Brook to its floodplain, including backwaters, ponds, native tree planting

Can the road be elevated above the river so a culvert isn't required. Shading would still be a problem, but less enhancements would be required to mitigate

Can the road go in a tunnel underneath the river retaining the floodplain and river

Concentrate on Old Brook?
Fairly poor.

Use local knowledge, existing data u/s and d/s

INNS
management
on both
streams
